Finite state transducers

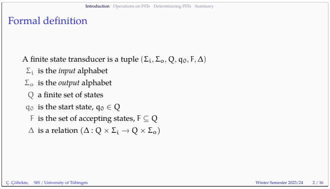
A quick introduction

- A *finite state transducer* (FST) is a finite state machine where transitions are conditioned on pairs of symbols
- The machine moves between the states based on an *input* symbol, while it outputs the corresponding *output* symbol
- An FST encodes a *relation*, a mapping from a set to another
- The relation defined by an FST is called a *regular* (or *rational*) relation

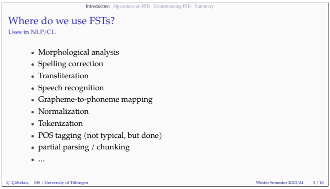
babba → babbb
aba → bbb
aba → abb



Formal definition

A finite state transducer is a tuple $(\Sigma_i, \Sigma_o, Q, q_0, F, \Delta)$

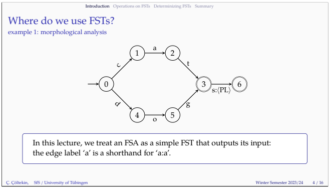
Σ_i is the *input* alphabet
Σ_o is the *output* alphabet
Q a finite set of states
q_0 is the start state, $q_0 \in Q$
F is the set of accepting states, $F \subseteq Q$
Δ is a relation $(\Delta : Q \times \Sigma_i \to Q \times \Sigma_o)$



Where do we use FSTs?

Uses in NLP/CL

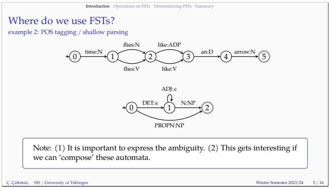
- Morphological analysis
- Spelling correction
- Transliteration
- Speech recognition
- Grapheme-to-phoneme mapping
- Normalization
- Tokenization
- POS tagging (not typical, but done)
- partial parsing / chunking
- ...



Where do we use FSTs?

example 1: morphological analysis

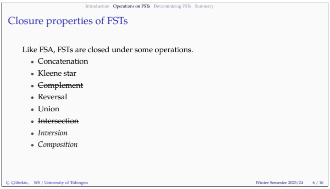
In this lecture, we treat an FSA as a simple FST that outputs its input: the edge label ‘a’ is a shorthand for ‘a:a’.



Where do we use FSTs?

example 2: POS tagging / shallow parsing

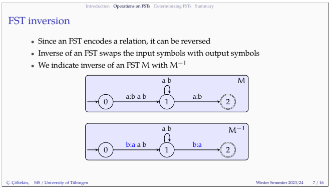
Note: (1) It is important to express the ambiguity. (2) This gets interesting if we can ‘compose’ these automata.



Closure properties of FSTs

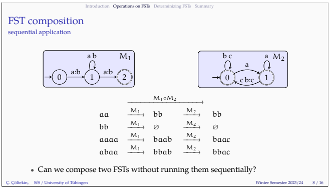
Like FSA, FSTs are closed under some operations.

- Concatenation
- Kleene star
- ~~Complement~~
- Reversal
- Union
- ~~Intersection~~
- *Inversion*
- *Composition*



FST inversion

- Since an FST encodes a relation, it can be reversed
- Inverse of an FST swaps the input symbols with output symbols
- We indicate inverse of an FST M with M^{-1}



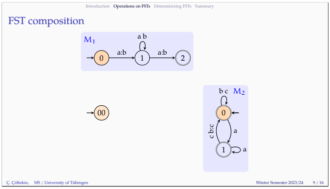
FST composition

sequential application

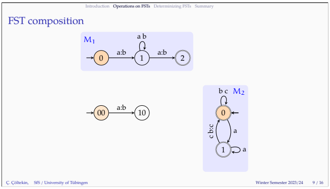
$$\xrightarrow{\quad M_1 \circ M_2 \quad}$$

$$aa \xrightarrow{M_1} bb \xrightarrow{M_2} bb$$
$$bb \xrightarrow{M_1} \varnothing \xrightarrow{M_2} \varnothing$$
$$aaaa \xrightarrow{M_1} baab \xrightarrow{M_2} baac$$
$$abaa \xrightarrow{M_1} bbab \xrightarrow{M_2} bbac$$

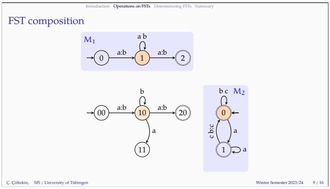
- Can we compose two FSTs without running them sequentially?



FST composition

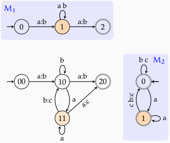


FST composition

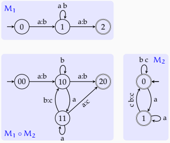


FST composition

FST composition



FST composition

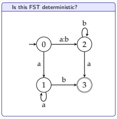


Projection

- *Projection* turns an FST into a FSA, accepting either the input language or the output language

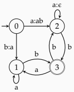
FST determinization

- A deterministic FST has unambiguous transitions from every state on any *input* symbol
- We can extend the subset construction to FSTs
- Determinization of FSTs means converting to a *subsequential* FST
- However, not all FSTs can be determinized



Sequential FSTs

- A sequential FST has a single transition from each state on every *input* symbol
- Output symbols can be strings, as well as ϵ
- The recognition is linear in the length of input
- However, sequential FSTs do not allow ambiguity



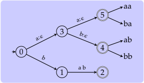
Subsequential FSTs

- A *k-subsequential* FST is a sequential FST which can output up to k strings at an accepting state
- Subsequential transducers allow limited ambiguity
- Recognition time is still linear

- The 2-subsequential FST above maps every string it accepts to two strings, e.g.,
  - baa → bba
  - baa → bbbb

An exercise

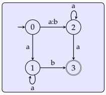
Convert the following FST to a subsequential FST



Determinizing FSTs

Another example

Can you convert the following FST to a subsequential FST?



Note that we cannot ‘determine’ the output on first input until reaching the final input.

FSA vs FST

- FSA are *acceptors*, FSTs are *transducers*
- FSA accept or reject their input, FSTs produce output(s) for the inputs they accept
- FSA define sets, FSTs define relations between sets
- FSTs share many properties of FSAs. However,
  - FSTs are not closed under intersection and complement
  - We can compose (and invert) the FSTs
  - Determinizing FSTs is not always possible
- Both FSA and FSTs can be weighted (not covered in this course)

Next:

- FSA and regular languages
- Parsing
