Winter Semester 2023/24

- · A trie (or prefix tree) is a tree-based data structure, particularly used for fast pattern matching
- Common applications include - Information retrieval: indexing large collections of texts based on keyword
 - Innormation retrieval: insecting large conections or sequences
 Storing lexicons and implementing 'autocomplete'
 As a replacement for hash tables
- Suffix trees, are particularly useful for solving a number of questions about strings efficiently

Tries - or 'standard' tries

- . A trie is a tree representation of a set of strings
 - Each node is associated with a character
- Tracing paths from root to the leaf odes produce each stri

- Shared prefixes in a trie is represented in common branch None of the string can be a prefix of another

Trios

- To prevent that no string is a p of another, a common trick is append a special end-of-string symbol
- Another approach is to mark the nodes that correspond to ends of

Searching in tries

with current character

• Fail: If there is no character to follow
 Input ends in a non-leaf node

 Accept if we are at a leaf node at the end of the input

Inserting, deleting and complexity

- . Search in a trie is clearly linear in the size of the string being searched There is a factor coming from the alphabet size q, but this can be reduced to
- $O(\log q)$ with binary search, or O(1) if a method allowing direct addressing is · Both in sertion and deletion starts with a lookup, and possibly inserts ne
- nodes or deletes them
- * All operations are similarly O(n) (neglecting the effect of the alphabet size)

Properties of tries

- . Internal nodes may have as many children as the number of symbols in the alphabet
- in practice this will be much smaller on average
 average degrees of nodes also go down as the depth incr . The height of the trie is the length of the longest string
- · Number of leaves are equal to the number of strings
- . In the worst case, the number of nodes is the total length of all strings

resulting in long chains

. In typical use, tries are sparse Tries can be compressed by replacing 'redundant' nodes with nodes labeled with substrings rath than characters

· Compressing tries saves space, and may also speed up some operations

Suffix tries (or suffix trees)

trie is linear

- . Suffix tries (or suffix trees) are tries that include all suff Suffix tries allow fast retrieval of any substring: substring search on a s
 - * They are used extensively in information retrieval
 - . They can also be adapted for wild card search and approximate search

Suffix tries

Compressed tries

. If the search ends in a leaf node, the pattern is a suffix of the string

. If there is a path from root to the end of the string, the pattern is in the string

· Suffix tries can also be co like the regular tries

Properties of suffix tries

- \star Standard suffix tries use $O(n^2)$ space, compression reduces space requirement to O(n)
- Space complexity can be reduced by keeping indexes to the string rather than the string itself in the (compressed) trie nodes
- Iterative insertion of suffixes result in a quadratic $(O(\mathfrak{q}\mathfrak{n}^2))$ construction time
- complexity
- There are linear time algor ing suffix tries
- Generalized suffix tries allow storing multiple strings (docu
- suffix trie (each string gets a special end-of-string marker)

Summary

its) in a single

- Trior are worful transbased data etractures
- * Their applications include set or map imple entations, storing diction
- Reading suggestion: Goodrich, Tamassia, and Goldwasser (2013, chapter 13)
- Regular languages and finite state a
- * Suggested reading: Jurafsky and Martin (2009, chapter 2)
